Experiment: Data Engineering Pipeline Overview

This experiment demonstrates Snowflake features specifically aligned to "Data Engineering" workload to build modern data pipelines. Data pipelines automate many of the manual steps involved in transforming and optimizing continuous data loads. Frequently, the "raw" data is firstloaded temporarily into a staging table used for interim storage and then transformed using a series of SQL statements before it is inserted into the destination reporting tables. The most efficient workflow for this process involves transforming only data that is new or modified.

Similar to previous portions of this experiment in the worksheets tab, click on the small, downward facing arrow, select "Load Script", then browse to the "ModernDataPipelines_Experiment.sql" file and select "Open".

Experiment 23: Streams

23.1 Creating Trips and Stations Streams on the Raw Data

23.1.1 Having built continuous data loading using Snowpipe, the next step is to create multiple Streams on the trips_raw table to track new trips and stations records. A stream object records the delta of change data capture (CDC) information for a table (such as a staging table), including inserts and other data manipulation language (DML) changes.

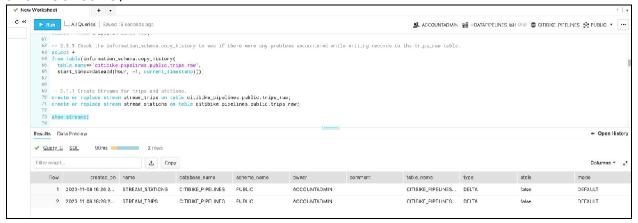

In a continuous data pipeline, table streams record when staging tables and any downstream tables are populated with data from business applications using continuous data loading and are ready for further processing using SQL statements

Streams provide a convenient way to ensure that you only process new records in the table each time.

```
create or replace stream stream_trips
on table
citibike_pipelines.public.trips_raw;
create or replace stream stream_stations
on table
citibike_pipelines.public.trips_raw;
```

show streams;

23.1.2Load 1 day of data to test the streams.

```
call stream data('2018-01-02', '2018-01-02');
```

23.1.3 Show the contents of the stage

```
list @streaming_data;
select $1 from @streaming data limit 100;
```

23.1.4 Check the status of the pipe and watch for file create events

```
select system$pipe status('trips pipe');
```

23.1.5 Snowpipe copies the data into our raw table...

```
select count(*) from
citibike_pipelines.public.trips_raw; select *
from citibike_pipelines.public.trips_raw limit
100;
```

and the insertions are tracked in the stream.

```
select count(*) from
stream_trips; select * from
stream_trips limit 100;
```

23.1.6 Clean up the stage by calling the purge_files function.

```
call purge files('trips raw', '@streaming data/');
```

23.1.7The data engineering process will process the streaming trips data, so next create tables to store those results.

```
create or replace table
 bike trips (tripduration
 integer,
 starttime
 timestamp ntz,
 stoptime
 timestamp ntz,
 start station id
 integer,
 end station id
 integer, bikeid
 integer,
 usertype string
);
create or replace table
 bike stations (station id
 integer,
 station name
 string,
 station latitude
 float,
 station longitude
 float,
 station comment
 string
);
```

The process flow will be:

Stream stream_trips -> table bike_trips (convert to structured, append new records)
Stream stream_stations -> table bike_stations (build a dimension table, merge new start and end stations)
